Backward Stochastic Differential Equations

- Settings:
 - A filtered complete probability space $(\Omega, \mathcal{F}, \mathbb{F}, \mathbb{P})$
 - $W := (W_t)_{0 \le t \le T}$ is a d-dimensional Brownian motion adapted to $\mathbb F$
- Forward Backward Stochastic Differential Equation

$$\begin{cases} dX_t = \mu(t, X_t)dt + \sigma(t, X_t)dW_t, X_0 = x_0, \\ dY_t = -f(t, X_t, Y_t, Z_t)dt + Z_t dW_t, Y_T = \Phi(X_T), \end{cases}$$

- $\mu: \Omega \times [0, T] \times \mathbb{R}^q \to \mathbb{R}^q$ and $\sigma: \Omega \times [0, T] \times \mathbb{R}^q \to \mathbb{R}^{q \times d}$
- $f: \Omega \times [0, T] \times \mathbb{R}^q \times \mathbb{R} \times \mathbb{R}^d \to \mathbb{R}$
- $\Phi: \Omega \times \mathbb{R}^q \to \mathbb{R}$
- Solution: (Y_t, Z_t) which satisfies the equation, adapts to \mathbb{F} and satisfies some regularity requirements.

Discretization

For a given time grid $\pi = \{0 = t_0 < ... < t_N = T\}$, we define the backward time discretizations (Y^{π}, Z^{π}) based on the theta-scheme from [Zhao et al., 2012]:

$$\begin{split} Y_{t_{N}}^{\pi} =& \Phi(X_{t_{N}}^{\pi}), \quad Z_{t_{N}}^{\pi} = \nabla \Phi(X_{t_{N}}^{\pi})\sigma(t_{N},X_{t_{N}}^{\pi}) \\ Z_{t_{k}}^{\pi} =& -\theta_{2}^{-1}(1-\theta_{2})\mathbb{E}_{t_{k}}\left[Z_{t_{k+1}}^{\pi}\right] + \frac{1}{\Delta_{k}}\theta_{2}^{-1}\mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{\pi}\Delta W_{k}^{T}\right] \\ &+ \theta_{2}^{-1}(1-\theta_{2})\mathbb{E}_{t_{k}}\left[f_{k+1}(Y_{t_{k+1}}^{\pi},Z_{t_{k+1}}^{\pi})\Delta W_{k}^{T}\right], \ k = N-1,\ldots,0 \\ Y_{t_{k}}^{\pi} =& \mathbb{E}_{t_{k}}\left[Y_{t_{k+1}}^{\pi}\right] + \Delta_{k}\theta_{1}f_{k}(Y_{t_{k}}^{\pi},Z_{t_{k}}^{\pi}) \\ &+ \Delta_{k}(1-\theta_{1})\mathbb{E}_{t_{k}}\left[f_{k+1}(Y_{t_{k+1}}^{\pi},Z_{t_{k+1}}^{\pi})\right], \ k = N-1,\ldots,0, \end{split}$$

where $f_k(y,z) := f(t_k, X^{\pi}_{t_k}, y, z)$, $0 \le \theta_1 \le 1$ and $0 < \theta_2 \le 1$.

イロト イポト イヨト イヨト

Discretization (cont.)

• Note that:

• the globally Lipschitz driver assumption is in force;

• we use a Markovian approximation $X_{t_k}^{\pi}, t_k \in \pi$:

•
$$X_{t_{k+1}}^{\pi} = X_{t_k}^{\pi} + b(t_k, X_{t_k}^{\pi})\Delta_k + \sigma(t_k, X_{t_k}^{\pi})\Delta W_k;$$

• due to the Markovian setting, there exist functions $y_k^{(\theta_1,\theta_2)}(x)$ and $z_k^{(\theta_1,\theta_2)}(x)$ such that

$$Y^{\pi}_{t_k} = y^{(heta_1, heta_2)}_k(X^{\pi}_{t_k}), \; Z^{\pi}_{t_k} = z^{(heta_1, heta_2)}_k(X^{\pi}_{t_k}).$$

Question:

How to approximate $\mathbb{E}_{t_k}^{\times} \left[y_{k+1}^{(\theta_1,\theta_2)}(X_{t_k+1}^{\pi}) \right]$, $\mathbb{E}_{t_k}^{\times} \left[y_{k+1}^{(\theta_1,\theta_2)}(X_{t_k+1}^{\pi}) \Delta W_k^{\mathcal{T}} \right]$, and other similar quantities along the time grid?

- Non-nested Monte Carlo scheme
 - It starts with the simulation of M independent samples of $(X_{t_k}^{\pi})_{0 \le k \le N}$, denoted by $(X_{t_k}^{\pi,m})_{1 \le m \le M, 0 \le k \le N}$.
 - The simulation is only performed once.

• The terminal values for each path are:

$$y_{N}^{(\theta_{1},\theta_{2}),R,I}(X_{t_{N}}^{\pi,m}) = \Phi(X_{t_{N}}^{\pi,m}),$$

$$z_{N}^{(\theta_{1},\theta_{2}),R}(X_{t_{N}}^{\pi,m}) = \nabla\Phi(X_{t_{N}}^{\pi,m})\sigma(t_{N},X_{t_{N}}^{\pi,m}), m = 1, \dots, M.$$

< < p>< < p>

Recurring steps in time (I)

- Non-nested Monte Carlo scheme
- Regress-later
 - The least-squares regression technique for functions is performed on the random variable $X_{t_{t+1}}^{\pi}$
 - Then we use the (analytical) expectation of the resulting approximation in our algorithm.
 - This will remove the "statistical" error at the regression step.
 - To ensure the stability of our algorithm, the regression coefficients must be bounded above.
 - It means that an error notion should be given by the program when the Euclidean norm of any regression coefficient vector is greater than a predetermined constant *L*.

Regress now and Regress later

• Regress now

$$\begin{pmatrix} \eta_1(X_{t_k}^{\pi,1}) & \eta_Q(X_{t_k}^{\pi,1}) \\ & \ddots & \\ \eta_1(X_{t_k}^{\pi,\#B}) & \eta_Q(X_{t_k}^{\pi,\#B}) \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_Q \end{pmatrix} = \begin{pmatrix} g(X_{t_{k+1}}^{\pi,1}) \\ \vdots \\ g(X_{t_{k+1}}^{\pi,\#B}) \end{pmatrix}$$
$$\mathbb{E}[g(X_{t_{k+1}}^{\pi})|X_{t_k}^{\pi} = x] \approx \sum_{l=1}^Q \alpha_l \eta_l(x)$$

• Regress later

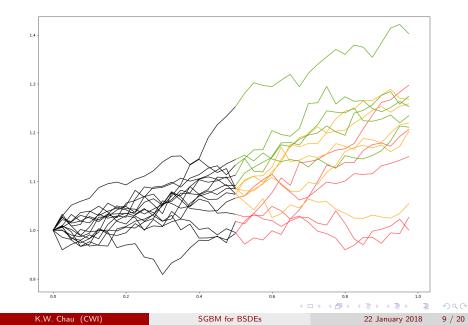

$$\begin{pmatrix} \eta_1(X_{t_{k+1}}^{\pi,1}) & \eta_Q(X_{t_{k+1}}^{\pi,1}) \\ & \ddots & \\ \eta_1(X_{t_{k+1}}^{\pi,\#B}) & \eta_Q(X_{t_{k+1}}^{\pi,\#B}) \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_Q \end{pmatrix} = \begin{pmatrix} g(X_{t_{k+1}}^{\pi,1}) \\ \vdots \\ g(X_{t_{k+1}}^{\pi,\#B}) \end{pmatrix}$$
$$\mathbb{E}[g(X_{t_{k+1}}^{\pi})|X_{t_k}^{\pi} = x] \approx \sum_{l=1}^{Q} \alpha_l \mathbb{E}[\eta_l(X_{t_{k+1}}^{\pi})|X_{t_k}^{\pi} = x]$$

K.W. Chau (CWI)

- Non-nested Monte Carlo scheme
- Regress-later
- Localization (Bundling)
 - At each time period, all paths are bundled into $\mathcal{B}_{t_k}(1), \ldots, \mathcal{B}_{t_k}(B)$ (almost) equal-size, non-overlapping partitions based on the result of $(X_{t_k}^{\pi,m})$.
 - We perform the approximation separately at each bundle.

< < p>< < p>

Bundling

Formulation

Specifically, the bundle regression parameters $\alpha_{k+1}(b)$, $\beta_{k+1}(b)$, $\gamma_{k+1}(b)$ are defined as

$$\begin{aligned} \alpha_{k+1}(b) &= \arg\min_{\alpha \in \mathbb{R}^{Q}} \frac{\sum_{m=1}^{M} (p(X_{t_{k+1}}^{\pi,m})\alpha - y_{k+1}^{(\theta_{1},\theta_{2}),R,I}(X_{t_{k+1}}^{\pi,m}))^{2} \mathbf{1}_{\mathcal{B}_{t_{k}}(b)}(X_{t_{k}}^{\pi,m})}{\sum_{m=1}^{M} \mathbf{1}_{\mathcal{B}_{t_{k}}(b)}(X_{t_{k}}^{\pi,m})} \\ \beta_{i,k+1}(b) &= \arg\min_{\beta \in \mathbb{R}^{Q}} \frac{\sum_{m=1}^{M} (p(X_{t_{k+1}}^{\pi,m})\beta - z_{i,k+1}^{(\theta_{1},\theta_{2}),R}(X_{t_{k+1}}^{\pi,m}))^{2} \mathbf{1}_{\mathcal{B}_{t_{k}}(b)}(X_{t_{k}}^{\pi,m})}{\sum_{m=1}^{M} \mathbf{1}_{\mathcal{B}_{t_{k}}(b)}(X_{t_{k}}^{\pi,m})} \\ \gamma_{k+1}(b) &= \\ \arg\min_{\gamma \in \mathbb{R}^{Q}} \frac{\sum_{m=1}^{M} (p(X_{t_{k+1}}^{\pi,m})\gamma - f_{k+1}(y_{k+1}^{(\theta_{1},\theta_{2}),R,I}, z_{k+1}^{(\theta_{1},\theta_{2}),R}))^{2} \mathbf{1}_{\mathcal{B}_{t_{k}}(b)}(X_{t_{k}}^{\pi,m})}{\sum_{m=1}^{M} \mathbf{1}_{\mathcal{B}_{t_{k}}(b)}(X_{t_{k}}^{\pi,m})} \end{aligned}$$

イロト イポト イヨト イヨト

Formulation (cont.)

The approximate functions within the bundle at time k are defined by :

$$\begin{aligned} z_{r,k}^{(\theta_1,\theta_2),R}(b,x) &= -\theta_2^{-1}(1-\theta_2)\mathbb{E}_{t_k}^{x} \left[p(X_{t_{k+1}}^{\pi}) \right] \beta_{k+1}(b) \\ &+ \theta_2^{-1} \mathbb{E}_{t_k}^{x} \left[\frac{\Delta W_{r,k}}{\Delta_k} p(X_{t_{k+1}}^{\pi}) \right] (\alpha_{k+1}(b) + (1-\theta_2)\Delta_k \gamma_{k+1}(b)), \\ y_k^{(\theta_1,\theta_2),R,0}(b,x) &= \mathbb{E}_{t_k}^{x} \left[p(X_{t_{k+1}}^{\pi}) \right] \alpha_{k+1}(b), \\ y_k^{(\theta_1,\theta_2),R,i}(b,x) &= \Delta_k \theta_1 f_k(y_k^{\pi,R,i-1}(x), z_k^{\pi,R}(x)) + h_k(x), \\ h_k(b,x) &= \mathbb{E}_{t_k}^{x} \left[p(X_{t_{k+1}}^{\pi}) \right] (\alpha_{k+1}(b) + \Delta_k(1-\theta_1)\gamma_{k+1}(b)), \quad i = 1, \dots, I, \end{aligned}$$

with

$$y_{k}^{(\theta_{1},\theta_{2}),R,I}(x) = \sum_{b=1}^{B} \mathbf{1}_{x \in \mathcal{B}_{t_{k}}(b)} y_{k}^{(\theta_{1},\theta_{2}),R,I}(b,x)$$

and similarly for z.

Refined Regression

Theorem 1

Assume that for a real function v that is bounded in a compact set and $\int v^2(x)\nu(dx) \leq \infty$, then

$$\begin{split} & \hat{\mathbb{E}}_{\mathcal{S}}\left[\iint |v(y) - \tilde{v}(x,y)|^{2}\nu(dx,dy)\right] \\ \leq & \frac{\vartheta(\mathcal{L}')}{\hat{\mathbb{E}}[\mathbf{1}_{\mathcal{S}}]} \hat{\mathbb{E}}\left[\sum_{B \in \mathbb{B}} \int_{B} \int \nu(dx,dy) \frac{(\log(\sum_{m=1}^{M} \mathbf{1}_{\mathcal{B}}(X^{m})) + 1)Q}{\sum_{m=1}^{M} \mathbf{1}_{\mathcal{B}}(X^{m})}\right] \\ & + \frac{8}{\hat{\mathbb{E}}[\mathbf{1}_{\mathcal{S}}]} \hat{\mathbb{E}}\left[\sum_{B \in \mathbb{B}} \int_{B} \int \nu(dx,dy) (\inf_{\phi \in H} \sup_{x \in B} \mathbb{E}\left[|v(Y) - \phi(Y)|^{2}|X = x\right] \wedge \mathcal{L}')\right] \\ & + \hat{\mathbb{E}}_{\mathcal{S}}\left[\iint |v(y) - \tilde{v}(x,y)|^{2}(1 - \mathbf{1}_{\mathcal{A}}(y))\nu(dx,dy)\right] \end{split}$$

3

(日) (同) (三) (三)

Example 1

We consider the BSDE:

$$\begin{cases} dX_t = dW_t, \\ dY_t = -(Y_t Z_t - Z_t + 2.5Y_t - \sin(t + X_t)\cos(t + X_t)) \\ -2\sin(t + X_t))dt + Z_t dW_t, \end{cases}$$

with the initial and terminal conditions $x_0 = 0$ and $Y_T = sin(X_T + T)$. The exact solution is given by

$$(Y_t, Z_t) = (\sin(X_t + t), \cos(X_t + t)).$$

The terminal time is set to be T = 1 and $(Y_0, Z_0) = (0, 1)$. We run the examples with the basis functions $\eta(x) = (1, x, x^2)$ and bundle based on the value of x.

Example 2: European option

We consider a market where the assets satisfy:

$$dS_{i,t} = \mu_i S_{i,t} dt + \sigma_i S_{i,t} dB_{i,t}, \ 1 \le i \le q$$

with B_t being a correlated q-dimension Wiener process with

$$dB_{i,t}dB_{j,t} = \rho_i j dt.$$

The parameters ρ_{ij} form a symmetric matrix ρ ,

$$\rho = \begin{pmatrix} 1 & \rho_{12} & \rho_{13} & \cdots & \rho_{1q} \\ \rho_{21} & 1 & \rho_{23} & \cdots & \rho_{2q} \\ \vdots & \vdots & \vdots & & \vdots \\ \rho_{q1} & \rho_{q2} & \rho_{q3} & \cdots & 1 \end{pmatrix},$$

and we assume it is invertible. By performing a Cholesky decomposition on ρ such that $LL^T = \rho$, we relate B_t to standard Brownian motion

$$B_t = LW_t.$$

K.W. Chau (CWI)

イロト 不得下 イヨト イヨト

For a European option with terminal payoff $g(S_t)$, a replicating portfolio Y_t , containing $\omega_{i,t}$ of asset $S_{i,t}$ and $Z_t = (\omega_{1,t}\sigma_1 S_{1,t}, \dots, \omega_{q,t}\sigma_q, S_{q,t})L$ solve the BSDE,

$$\begin{cases} dY_t = -\left(-rY_t - Z_t L^{-1}\left(\frac{\mu - r}{\sigma}\right)\right) dt + Z_t dW_t; \\ Y_T = g(S_T), \end{cases}$$

where $\left(\frac{\mu-r}{\sigma}\right) = \left(\frac{\mu_1-r}{\sigma_1}, \cdots, \frac{\mu_q-r}{\sigma_q}\right)^{I}$. In this numerical test, we use the 5-dimensional example from [Reisinger and Wittum, 2007].

Example 2: European option (cont.)

We would consider a European weighted basket put option for 1 year in our test, therefore, the payoff function g is given by

$$g(s) = \left(1 - \sum_{i=1}^5 w_i s_i\right)^+,$$

where $(w_1, w_2, w_3, w_4, w_5) = (38.1, 6.5, 5.7, 27.0, 22.7)$. The reference price is given as 0.175866. We use equal-partitioning and sorting the paths according to $\sum_{i=1}^{5} w_i X_{t_{\rho,i}}^m$.

The regression basis is $p_k(x) = \left(\sum_{i=1}^5 w_i x_i\right)^{k-1}$ for $k = 1, \dots, K$.
