

# Towards a uniform analysis of *any*\*

Robert van Rooij

**Abstract.** In this paper, Universal *any* and Negative Polarity Item *any* are uniformly analyzed as ‘counterfactual’ donkey sentences (in disguise). Their difference in meaning is reduced here to the distinction between *strong* and *weak* readings of donkey sentences. It is shown that this explains the *universal* and *existential* character of Universal- and NPI-*any*, respectively, and the positive and negative contexts in which they are licensed. Our uniform analysis extends to the use of *any* in command and permission sentences. It predicts that whereas the use of *any* in permission sentences is licensed and gives rise to a universal reading, it is not licensed in command sentences.

**Keywords:** Any, counterfactuals, free choice, negative polarity

## 1. Introduction

The word ‘any’ is one of the most discussed items in theories of natural language form and interpretation. What does the word mean, and why can it be used appropriately, or even grammatically, only in a very limited set of grammatical contexts? Even more challenging, perhaps, is the question whether we can give a ‘uniform’ enough analysis of U(niversal) *any*, N(egative) P(olarity) I(tem) *any*, and F(ree) C(hoice)

---

\* This paper was presented in Amsterdam, Frankfurt, and Hamburg, and I would like to thank the audiences of these talks and the reviewers for their comments and suggestions. Van Rooij (2006b) is an early version of this paper.

*any*<sup>1</sup> that can account for their differences in meaning, but still explains why these different meanings are expressed (at least in English) by the same word. In this paper I will argue in favor of an analysis of all these uses of *any* as ‘counterfactual’ donkey sentences (in disguise).<sup>2</sup> The difference between U-*any* and NPI-*any* will be reduced to the distinction between *strong* and *weak* readings of donkey sentences. I will show that this explains the *universal* and *existential* character of U- and NPI-*any*, respectively, and the positive and negative contexts in which they are licensed. FC-*any* will be analyzed like NPI-*any* and its universal force will be accounted for in terms of a new performative analysis of permission sentences.

This paper is organized as follows: In Sect. 2, I will motivate and explain Kadmon and Landman’s (1993) widening and strengthening analysis of *any*. In Sect. 3 I will explain van Rooij’s (2006a) analysis of (strong readings of) counterfactual donkey sentences, and in Sect. 4 I will analyze Universal *any* in terms of it. Sect. 5 will deal with NPI-*any*.

---

<sup>1</sup> U-*any* is normally identified with FC-*any*. As will become clear in the rest of this paper, I believe there is good reason to separate them.

<sup>2</sup> It will turn out that my analysis of the various uses of *any* does not always crucially involve counterfactual worlds. For this reason, a reviewer suggested to change terminology. I see the force of this suggestion, but I have decided to keep on using the phrase ‘counterfactual’, though now making use of quotation marks. The reasons for this are two: first, the standard ordering relation used to represent the meaning of counterfactual conditionals plays a crucial role in my analysis; second, I want to make clear that the proposal is built on my earlier analysis of counterfactual donkey sentences (van Rooij 2006a).

It will be shown that if we treat this item as a weak ‘counterfactual’ donkey sentence, the meaning of NPI-*any* will turn out to be equivalent to a standard indefinite, but one that can be used appropriately (via Kadmon and Landman’s licensing conditions) almost only in negative contexts. In Sect. 6 I discuss the use of *any* in permission sentences and explain why FC-*any* is licensed in permissions, but not in commands. I conclude in Sect. 7 with briefly comparing my proposal with some others.

## 2. The widening analysis of *any*

Ladusaw (1979) proposed a very successful *semantic* characterization of the contexts in which *any* can be used appropriately: as far as *any* is a negative polarity item it can be used appropriately, or is *licensed*, only in *downward entailing* contexts. Context  $X - Y$  is downward entailing (DE) iff from the truth of  $X\alpha Y$  and the fact that  $\llbracket\beta\rrbracket \subseteq \llbracket\alpha\rrbracket$  (where  $\llbracket\alpha\rrbracket$  denotes the semantic meaning of expression  $\alpha$ ) we can conclude the truth of  $X\beta Y$ . Thus, a context is DE iff an expression occurring in it can be replaced by a semantically stronger expression *salva veritate*.

Although Ladusaw’s characterization of the contexts in which *any* can occur appropriately is quite successful, his proposal can’t be the whole story. First, *any* sometimes has a ‘universal’ reading, and if it does, it can occur in a non-DE context.

- (1) a. *Any* owl hunts mice.  
 b. *Any* farmer who owns a donkey beats it.

- c. John talked to *any* woman who came up to him.

Second, although the DE analysis might give a reasonably good *description* of the contexts that license NPI-*any*, it does not *explain* why they do so and it takes the meaning of the item itself to be irrelevant.

Kadmon and Landman (1993) (henceforth K&L) account for these problems by taking the meaning of *any* into account.<sup>3</sup> They argue that an NP of the form *any CN* should be interpreted like the corresponding indefinite *a CN*, but where the domain of quantification over which the indefinite with *any* ranges is *wider* than the domain of *a CN*, and where the sole difference between NPI-*any* and U-*any* lies in the fact that the latter, but not the former, is interpreted generically. Moreover, K&L propose an explanation for why NPI-*any* is licensed only in DE contexts. This proposal involves a second meaning contribution of *any*: the interpretation of the sentence after domain widening has to be *stronger* than before widening. Consider (2-a) versus (2-b):

- (2) a. \*John ate *anything*.  $\exists x Ate(j, x)$   
 b. John didn't eat *anything*.  $\neg \exists x Ate(j, x)$

Sentence (2-a) is unacceptable, but its negation (2-b) is not. Because extension of the domain over which (kind of) things John might eat would make 'John ate something' only weaker, i.e. less informative, (2-a) is correctly predicted to be unacceptable. Sentence (2-b), on the other

---

<sup>3</sup> Krifka (1995) develops a very similar approach independently. Both approaches seek to solve other problems of Ladusaw's analysis as well, but we won't bother about that in this paper. In this paper I use K&L's analysis, although I believe that Krifka's analysis would do equally well.

hand, gets a stronger, more informative, interpretation after domain widening, and is thus predicted to be acceptable. Thus, the licensing of NPI-*any* in DE contexts does not have to be stipulated, but falls out as a ‘theorem’ of their analysis.

K&L’s widening analysis of *any* is attractive and seems to be just what we need for NPI-*any*.<sup>4</sup> As noted by Dayal (1998), however, the proposal is more problematic for U-*any*. Recall that K&L propose that *any* should have the same meaning as the corresponding indefinite, and gets a universal interpretation in positive contexts just in case the corresponding indefinite is read generically. Dayal notes that this is not quite right: whereas (1-c) clearly has a universal interpretation, the same sentence with the corresponding indefinite, i.e. (3), does not have a generic reading.

(3) John talked to *a* woman who came up to him.

Moreover, while generics allow for exceptions, sentences with U-*any* don’t. This strongly suggests that U-*any* should not be thought of as being a standard indefinite that receives a generic interpretation. But this gives rise to the question how, then, to account for the universal readings of *any* in (1-a)-(1-c)? Dayal (1998) suggests to give up on K&L’s

---

<sup>4</sup> K&L also shows that the widening + strengthening account can explain the licensing of NPI-*any* in some other contexts than just the DE-ones. Krifka (1995) and van Rooij (2003) show that it can explain the licensing of NPIs in questions, while Heim (1984) and van Rooij (2006a) show (in different ways) that it accounts for the occurrence of *any* in antecedents of counterfactual conditionals as well.

uniform analysis of *any* and proposes that in contrast to NPI-*any*, U-*any* denotes a universal quantifier. However, to account for the fact that (4-a) has an additional ‘that-can’t-be-an-accident’-interpretation not shared by (4-b), she claims that U-*any* is a special kind of quantifier: it quantifies over *possible* rather than *actual* individuals.

- (4) a. *Any* student in Mary’s class is working on NPIs.  
 b. *Every* student in Mary’s class is working on NPIs.

The intuitions Dayal wants to account for are real, but one wonders whether we really have to give up on a uniform analysis of *any*. We here propose that this is not needed if we analyze both *any*’s as ‘*counterfactual donkeys* (in disguise).<sup>5</sup>

### 3. Counterfactual donkey sentences

#### 3.1. COUNTERFACTUALS

Stalnaker (1968) and Lewis (1973) gave the following well-known analysis of (counterfactual) conditional sentences represented by  $\phi > \psi$ :

$\phi > \psi$  is true at  $w$  if some  $\phi \wedge \psi$ -worlds are closer to  $w$   
 than any  $\phi \wedge \neg\psi$ -worlds.

The notion ‘closer  $\phi$ -world to  $w$  than’ can be explained in terms of an ordering relation on the accessible worlds (but let us assume that

---

<sup>5</sup> For a discussion of other proposals, see Sect. 7.

all worlds are accessible). The ordering relation ‘ $\leq_w$ ’ between worlds is required to obey the following conditions: reflexivity, transitivity, connectedness, and strong centering.<sup>6</sup> The intuitive meaning of  $v \leq_w u$  is that  $v$  is at least as close, or similar, to  $w$  as  $u$  is. Accepting the limit assumption, i.e.,  $[\phi] \neq \emptyset \Rightarrow \{v \in [\phi] : \forall u \in [\phi] : v \leq_w u\} \neq \emptyset$  (or limiting our analysis to the finite case), we can reformulate the semantics of counterfactuals in terms of a selection function. Let us define a selection function  $f$  in terms of the similarity relation as follows:  $f_w([\phi]) = \{v \in [\phi] \mid \forall u \in [\phi] : v \leq_w u\}$ . The proposition expressed by the conditional  $\phi > \psi$  is now the following set of possible worlds:

$$[\phi > \psi] \stackrel{def}{=} \{w \in W : f_w([\phi]) \subseteq [\psi]\}$$

That is,  $\phi > \psi$  is true in  $w$  iff  $\psi$  is true at every closest  $\phi$ -world to  $w$ .<sup>7</sup>

### 3.2. DONKEY SENTENCES

Lewis and Stalnaker assumed that the meaning of a sentence can be represented adequately by a set of possible worlds. It is well known,

<sup>6</sup> Reflexive: for all  $v : v \leq_w v$ . Transitive: for all  $v, u$  and  $x$ : if  $v \leq_w u$  and  $u \leq_w x$ , then  $v \leq_w x$ . Connected: for all  $v$  and  $u$ ,  $v \leq_w u$  or  $u \leq_w v$ . Strong centering: for all  $v : w \neq v \Rightarrow (w \leq_w v \text{ and } v \not\leq_w w)$ .

<sup>7</sup> Of course, Stalnaker’s analysis is still stronger, because he makes the additional assumption that for all  $[\phi] \subseteq W$  and  $w \in W$ ,  $f_w([\phi])$  is always a singleton set. In terms of the similarity relation between worlds, this means that Stalnaker assumes that  $<_w$  obeys trichotomy: for all  $u, v : u <_w v$  or  $v <_w u$  or  $u = v$ .

however, that this leads to problems for the analysis of indefinites and pronouns, especially in donkey sentences. Of course, Kamp (1981) and Heim (1982) showed that we could maintain a uniform analysis of indefinites and pronouns and still get the truth conditions of donkey sentences right, while Groenendijk and Stokhof (1991) and others have demonstrated that such an analysis need not threaten compositionality if we are willing to change our static possible-world conception of the meaning of a sentence. According to the alternative dynamic view, we interpret sentences with respect to a context that is represented by a set of world-assignment pairs, and the meaning of the sentence itself can be thought of as the update of this context, where possibilities are *eliminated* when the sentence is false, and the assignment of the possibilities is *enriched* if a new variable, or discourse referent, is introduced by way of an indefinite.<sup>8</sup> According to this analysis, the formula  $\exists x[Px] \rightarrow Qx$  is predicted to be equivalent with  $\forall x[Px \rightarrow Qx]$ , which means that we can account for (standard) donkey sentences in a systematic and compositional way.

### 3.3. COUNTERFACTUAL DONKEYS

In standard indicative donkey sentences it is unproblematic to assume that the conditional connective should be interpreted as material implication. But donkey sentences show up not only in indicative mood; we have counterfactual donkey sentences as well:

- (5) If John owned a donkey, he would beat it.

---

<sup>8</sup> I assume here that assignments are partial functions.

Representing counterfactuals as  $\phi > \psi$  like before, we would like to represent (5) abstractly as  $\exists x[Px] > Qx$ , while still maintaining the equivalence with  $\forall x[Px > Qx]$ . The challenge is to account for this equivalence, without giving up our standard dynamic account of indefinites. In van Rooij (2006a) it is shown how this challenge can be met, and I will repeat the argumentation from that paper here.<sup>9</sup>

Suppose that we want to interpret a sentence of the form  $\exists x\phi > \psi$  in possibility  $\langle w, g \rangle$ . According to the standard Lewis/Stalnaker analysis of counterfactuals, we should then select among those possibilities that verify  $\exists x\phi$  the ones that are closest to  $\langle w, g \rangle$  and check whether they also make  $\psi$  true. Because  $\phi$  might contain free variables that should be interpreted by means of  $g$ , the natural context of interpretation of  $\exists x\phi$  is the set  $W(g) = \{\langle v, h \rangle : v \in W \ \& \ h = g\}$ .<sup>10</sup> After the interpretation of  $\exists xPx$ , for instance, we end up with a set of world-assignment pairs like  $\langle v, h \rangle$ , where variable  $x$  is in the domain of assignment  $h$ , and  $h(x)$  is an element of the set denoted by  $P$  in world  $v$ . Let us denote this set of world-assignment pairs by  $/\exists xPx/g$ . To check whether  $\exists x[Px] > Qx$  is true in  $\langle w, g \rangle$  we have to select among the possibilities in  $/\exists xPx/g$  those that are closest to  $\langle w, g \rangle$ , and see whether they also verify  $Qx$ . But

---

<sup>9</sup> This treatment of counterfactual donkey sentences was crucially inspired by Alonso-Ovalle's (2005) analysis of counterfactuals with disjunctive antecedents.

<sup>10</sup> For simplicity we can assume that all worlds have the same domain, but this is quite inessential, because we could also make use of counterpart functions from individuals and worlds to individuals. It is implicitly assumed that  $W$  denotes the set of *all* worlds. This need not always be the case, though.

this means that we need an ordering relation,  $\leq_{\langle w, g \rangle}^*$ , between world-assignment pairs with respect to possibility  $\langle w, g \rangle : \langle u, k \rangle \leq_{\langle w, g \rangle}^* \langle v, h \rangle$ . Fortunately, there is a natural way to define an ordering ' $\leq^*$ ' between world-assignment pairs in terms of the ordering relation between worlds used by Lewis and Stalnaker:<sup>11</sup>

**Definition 1** Given a Lewis/Stalnaker similarity relation  $\leq_w$  between worlds, we define the similarity relation  $\leq_{\langle w, g \rangle}^*$  between world-assignment pairs as follows:

$$\langle v, h \rangle \leq_{\langle w, g \rangle}^* \langle u, k \rangle \text{ iff}_{def} h = k \supseteq g \text{ and } v \leq_w u.$$

Notice, first, that in case the antecedent  $\phi$  of a counterfactual doesn't introduce new variables, or discourse markers, all the elements of  $/\phi/g$  are world-assignment pairs with assignment  $g$ . Thus, in that case ' $\leq^*$ ' comes down to ' $\leq$ ', because we can now ignore the assignment function. But suppose that  $\phi$  is of the form  $\exists xPx$ . In that case, all the assignments in  $/\exists xPx/g$  differ from  $g$  in that they also assign an object to  $x$ . Let  $\langle v, h \rangle$  and  $\langle u, k \rangle$  be two possibilities in  $/\exists xPx/g$ . According to definition 1, to check whether one of these is more similar to  $\langle w, g \rangle$  than the other only makes sense in case  $h$  assigns the same individual to  $x$  as  $k$  does,  $h(x) = k(x)$ .<sup>12</sup> But this means that we must check for *each*

---

<sup>11</sup> The same ordering has been used in Schulz and van Rooij (2006a) to account, for instance, for the intuition that the answer 'John came, Mary came, or both came' to the question 'Who came?' does not give rise to an inconsistency, although it should be interpreted in a global exhaustive way.

<sup>12</sup> Though the relation ' $\leq_w$ ' is connected, ' $\leq_{\langle w, g \rangle}^*$ ' is not.

individual  $d$  separately what are the closest possibilities to  $\langle w, g \rangle$  that make  $Px$  true. We define the selection function as follows:

**Definition 2** Given a similarity relation  $\leq_{\langle w, g \rangle}^*$  between world-assignment pairs as defined in definition 1 and a standard dynamic update function  $[\cdot]$ , we define the selection function  $f^*$  from sets of world-assignment pairs to sets of world-assignment pairs as follows:

$$f_{\langle w, g \rangle}^*(/\phi/g) \stackrel{def}{=} \{\langle v, h \rangle \in /\phi/g \mid \neg \exists \langle u, k \rangle \in /\phi/g, \langle u, k \rangle <_{\langle w, g \rangle}^* \langle v, h \rangle\},$$

where  $/\phi/g \stackrel{def}{=} [\phi](\{\langle v, h \rangle : v \in W \ \& \ h = g\})$ , and

$$j <_i^* k \text{ iff}_{def} j \leq_i^* k \text{ but not } k \leq_i^* j.$$

It is easy to see that it now follows that  $f_{\langle w, g \rangle}^*(/\exists x Px/g)$  comes out to be equivalent with  $\bigcup_{d \in D} f_{\langle w, g \rangle}^*(\{\langle v, g[x/d] \rangle : d \in I_v(P)\})$ . On our assumption that  $\phi > \psi$  is true in  $\langle w, g \rangle$  iff  $\forall \langle v, h \rangle \in f_{\langle w, g \rangle}^*(/\phi/g) : \langle v, h \rangle$  verifies  $\psi$ , we end up with the happy result that  $\exists x[Px] > Qx$  is equivalent with  $\forall x[Px > Qx]$ .<sup>13</sup> I conclude that we can account for counterfactual donkey sentences in a natural and compositional way.

---

<sup>13</sup> To be sure, this equivalence holds for many-ary donkey sentences as well: if  $\vec{x}$  is an  $n$ -ary tuple of variables and  $\phi$  and  $\psi$  are  $n$ -ary predicates, our analysis predicts that  $\exists \vec{x}[\phi(\vec{x})] > \psi(\vec{x})$  is equivalent with  $\forall \vec{x}[\phi(\vec{x}) > \psi(\vec{x})]$ .

#### 4. Universal *any* as a ‘counterfactual’ donkey

Notice that for  $\exists x[Px] > Qx$  to be true in world  $w$  where  $P$  has a non-empty extension it is not enough that all individuals in the extension of  $P$  also have property  $Q$ : it must also be the case for all non- $P$  individuals that they would have property  $Q$  if they had property  $P$ . Thus,  $\exists x[Px] > Qx$  is *stronger* than  $\forall x[Px \rightarrow Qx]$ . This last feature suggests that we can account for the extra ‘that-can’t-be-an-accident’-interpretation of U-*any* when we think of it as a ‘counterfactual’ donkey in disguise.

The idea is to translate Dayal’s *any* in a (dynamic) Montague-style framework (with connective ‘>’) by ‘ $\lambda P\lambda Q\exists x[Px] > Qx$ ’.<sup>14,15</sup> Notice, first, that on such an analysis, (1-a), *Any owl hunts mice*, is interpreted as a kind of generic statement, though without exceptions, and that on this analysis (1-b), *Any farmer who owns a donkey beats it*, is treated as a standard (though ‘counterfactual’) donkey sentence, without any further problems. Second, on this analysis (4-a), *Any student in Mary’s class is working on NPIs*, has a stronger meaning than (4-b), *Every*

---

<sup>14</sup> Our earlier claim that  $\exists x[Px] > Qx$  is equivalent with  $\forall x[Px > Qx]$  was based on the implicit assumption that every world has the same domain. In case we don’t make that assumption, the equivalence only holds if the universal quantifier quantifies over *possible* individuals. This shows that our proposal is indeed close to Dayal’s analysis.

<sup>15</sup> Independently, Kim and Kaufman (2006) proposed to treat some Korean Indeterminate-*Na* items in terms of a similarity relation between worlds as well. It would be interesting to see how the proposals relate to each other.

*student in Mary's class is working on NPIs*, because (4-a) has the extra 'that-can't-be-an-accident'-interpretation.<sup>16</sup> Remember that to account for this effect, we don't have to quantify over possible individuals.

A problem for any analysis of *any* is that it should be able to account for the fact that whereas (6-a) is not appropriate, (6-b) is:

- (6) a. \*Yesterday, John talked to *any* woman.  
 b. Yesterday, John talked to *any* woman *he saw (yesterday)*.

What has to be explained is how it can be that the extra 'he saw (yesterday)' added to the restrictor of *any* turns the inappropriate (6-a) into the appropriate (6-b). According to Dayal (1998), (6-a) is inappropriate because it gives rise to too strong truth conditions. Her analysis involves the proposal that *U-any* universally quantifies over *possible* instead of *actual* individuals. We don't quantify over possible individuals but can still account for the inappropriateness of (6-a) by our 'counterfactual' treatment of *any*: (6-a) would be interpreted as saying that 'for all individuals, if he/she were a woman, John would have talked to him/her yesterday'. According to our analysis, this can only be the case if John talked yesterday not only to all existing women, but also to every non-existing woman, which is an obviously false claim. For

---

<sup>16</sup> The difference between the meaning of *any* and *every* disappears, on our analysis, if the restricting noun of the quantifier is 'empty'. Thus, *Anybody smokes* is predicted to mean the same as *Everybody smokes*. I take it that the former sentence is less appropriate than the latter, and would like to account for that by noticing that there is a more standard alternative (the sentence with *every*) with the same meaning.

this reason, I propose, (6-a) is inappropriate. This is all fine, but why, then, is (6-b) suddenly appropriate? Dayal (1998) argues that this is due to the episodic character of the extra ‘he saw (yesterday)’ added to the restrictor. Again, we will follow Dayal. If we assume that the extra material ‘he saw yesterday’ should be interpreted in the actual world,<sup>17</sup> this means that *any* in (6-b) now quantifies only over individuals John *actually* saw (yesterday). As a result, (6-b) will be interpreted as saying that ‘for all individuals John *actually* saw (yesterday), if he/she were a woman, John would have talked to him/her yesterday’.<sup>18</sup> But then, (6-b) becomes a statement with very modest truth conditions,<sup>19</sup> and there is no pragmatic reason anymore to deem it inappropriate.

In this section we have dismissed K&L’s analysis of U-*any* as a generic indefinite. This doesn’t mean, however, that I would like to give up their constraint on appropriate use of U-*any* as well. In fact, adopting their constraint gives rise to an interesting consequence. Recall that K&L propose that *any* can be used appropriately only if domain widening results in a *stronger* assertion. Let us say that  $\exists x_D[Px]$  means that the domain of quantification of ‘ $\exists$ ’ is restricted to individuals in  $D$ . Observe now that if  $D' \subset D$ , it immediately follows

---

<sup>17</sup> Accounted for either by a two-dimensional actuality operator or by a two-sorted logical language that allows for quantification over worlds in the object language. See also Chierchia (2006).

<sup>18</sup> Thanks to a reviewer for pointing out a problem with an earlier, slightly different proposal.

<sup>19</sup> Though it still has a stronger meaning than the universal ‘Yesterday, John talked to *every* woman he saw.’

that  $\exists x_D [Px] > q$  is stronger than  $\exists x_{D'} [Px] > q$ . This is so because  $\exists x_{\{d_1, d_2\}} [Px] > q$ , for example, comes out as being equivalent with  $(P(d_1^*) > q) \wedge (P(d_2^*) > q)$ ,<sup>20</sup> while  $\exists x_{\{d_1\}} [Px] > q$  is equivalent with  $P(d_1^*) > q$ , and is thus weaker. Thus, it is predicted that U-*any* is appropriate in *positive* contexts. If we embed U-*any* under negation, however, domain extension leads to a weaker assertion,<sup>21</sup> which means that U-*any* is predicted to be appropriate *only* in positive contexts. I believe that this is in accordance with the facts.<sup>22</sup>

Let us remind ourselves what we have done in this section: we have accounted for Dayal's observations (or at least the ones mentioned in this paper) concerning U-*any* without having to give up the popular assumption that all uses of *any* should be handled by means of existential quantification. Although U-*any* is represented in terms of existential quantification, we still predict a universal reading and – via K&L's domain widening and strengthening – that U-*any* is appropriate only in positive contexts. The picture that emerges, then, is the following: *any* should always be represented in terms of an existential quantifier, and its use is appropriate just in case domain extension gives rise to a stronger assertion. For NPI-*any* we follow K&L and treat it standardly as  $\lambda P \lambda Q \exists x [Px \wedge Qx]$ , which means that it can be used appropriately

---

<sup>20</sup> Where  $d^*$  is a constant in the language that uniquely denotes  $d$ .

<sup>21</sup> This is obvious, because  $\neg(\exists x_{\{d_1, d_2\}} [Px] > q)$  is now equivalent with  $\neg(P(d_1^*) > q) \vee \neg(P(d_2^*) > q)$ , which is weaker than  $\neg(P(d_1^*) > q)$ , which is equivalent with  $\neg(\exists x_{\{d_1\}} [Px] > q)$ .

<sup>22</sup> The same prediction is made, of course, by anyone who accounts for U-*any* in terms of universal quantification like Dayal (1998, 2004) and Saeboe (2001).

(almost) only in DE contexts. For U-*any* we proposed the representation  $\lambda P\lambda Q\exists x[Px] > Qx$ , and we have seen that this results in the appropriateness condition that it can be used in positive contexts only.

## 5. NPI-*any* as a weak ‘counterfactual’ donkey

Although I find this emerging analysis appealing, it should be clear that we can’t be fully satisfied yet. First of all – as will be discussed in the final section – other authors have proposed a *conditional* analysis of U-*any* before, and so it is not clear what is won by our particular treatment making use of the counterfactual connective ‘>’. Second, the treatment suggested so far of U-*any* and NPI-*any* is not yet uniform enough: the connectives involved in the different uses of *any* are different, and we still have to admit that *any* is ambiguous. Without claiming that we can get rid of this ambiguity completely, I would like to propose that the different uses of *any* are almost identical, if we think of NPI-*any* from a ‘counterfactual’ donkey perspective as well. I will argue that the U- and NPI- uses of *any* are as closely related as the strong and weak readings of ‘counterfactual’ donkey sentences. In this section I will first present the analysis of *weak* counterfactual donkey sentences given in van Rooij (2006a), and then propose to treat NPI-*any* in terms of it.

### 5.1. WEAK COUNTERFACTUAL DONKEY SENTENCES

Although I believe that a counterfactual donkey sentence is mostly equivalent to a formula with wide scope universal quantification, there

are (at least) two types of examples where this equivalence seems dubious, or even obviously wrong:

- (7) a. If Alex were married to a girl from his class, it would be Sue.
- b. If I had a dime in my pocket, I would throw it into the meter.

For (7-a) to be true, it doesn't seem to be required that for any individual (e.g. Mary), if that individual were from Alex's class and married to him, it would be Sue. For this paper the second type of example, i.e (7-b), is more interesting. The indicative version of this example is of course the standard example that shows that not all donkey sentences give rise to universal readings.

The universal reading of donkey sentences in standard DRT, FCS, and dynamic semantics depends on the assumption of unselective binding. I made that assumption in Sects. 3 and 4 as well, by defining the ordering relation between world-assignment pairs as in definition 1. However, this gives rise to the problem of how we can account for weak readings of donkey sentences (the indicative version of (7-b)) and for asymmetric readings of adverbs of quantification (the proportion problem). The standard way to solve those problem in dynamic semantics (going back to Root 1986 and also defended in Dekker 1993) is to give up unselective binding for all variables involved. The idea is to quantify not over *individual* assignments, but rather over *equivalence classes* of assignment functions, and require that for the donkey sentence to be true there should be an element of each equivalence class of assignments

verifying the antecedent that makes the consequent true. Two different assignments are in the same equivalence class of assignment functions iff the variables with different values are not being selected over. The nice thing about this solution is that (i) one still treats all indefinites in the same way, and (ii) the indefinite whose introduced variable is not unselectively bound can still be picked up anaphorically in the consequent.

So, how does this work for counterfactual donkey sentences? Well, we will represent a counterfactual in general by a formula  $\phi >^X \psi$ , where  $\phi$  and  $\psi$  are as expected, and  $X$  is the set of variables introduced by  $\phi$  that is unselectively bound. Notice that even if  $\phi$  contains an indefinite,  $X$  might still be the empty set. Now let us slightly redefine the ordering relation between possibilities as follows:

**Definition 3** Given a Lewis/Stalnaker similarity relation  $\leq_w$  between worlds, we define the similarity relation  $\leq_{\langle w, g \rangle}^{*, X}$  between world-assignment pairs as follows:  $\langle v, h \rangle \leq_{\langle w, g \rangle}^{*, X} \langle u, k \rangle$  iff<sub>def</sub>  $h, k \supseteq g$ ,  $h \uparrow^X = k \uparrow^X$ , and  $v \leq_w u$ .

Here  $h \uparrow^X$  denotes the restriction of  $h$  to  $X$ , and thus conveys that  $h \uparrow^X = k \uparrow^X$  iff  $\forall x \in X : h(x) = k(x)$ . What this definition comes down to is a weakening of definition 1, because it now allows for a comparison between possibilities where the assignments are not the same. In particular, if  $X = \emptyset$  it immediately holds that the assignments are irrelevant for the ordering relation:  $\langle v, h \rangle \leq_{\langle w, g \rangle}^{*, \emptyset} \langle u, k \rangle$  iff  $v \leq_w u$ .

If one makes the assumption that one can only be married to one girl, this small, but independently motivated, change already accounts for

example (7-a) above, without making the assumption that indefinites are ambiguous. We redefine the selection function as follows:

**Definition 4**  $f_{\langle w, g \rangle}^{*, X}(/ \phi / g) = \{i \in / \phi / g : \neg \exists j \in / \phi / g : j <_{\langle w, g \rangle}^{*, X} i\}$ .

Now example (7-a) is predicted to be true if represented such that  $X = \emptyset$  just in case Alex is married to Sue (and only Sue) in the world(s) closest to the actual one where Alex is married to a(ny) girl from his class.

But what should we do to account for counterfactual variants of *weak* donkey sentences like (7-b)? To account for weak readings of counterfactual donkey sentences, we have to assume that there are possibilities closest to the actual world where I have more than one dime in my pocket. What is required to account for such cases is to lump together all of the possibilities where the difference in assignment doesn't matter, and say that only one of those assignments has to be taken into account for the interpretation of the consequent. Let us first say that  $\langle v, h \rangle \sim^X \langle u, k \rangle$  iff  $v = u$  and  $h \uparrow^X = k \uparrow^X$ . Then we give the following general truth conditions of conditionals:

**Definition 5**  $\phi >^X \psi$  is true in  $\langle w, g \rangle$  iff  $\forall \langle v, h \rangle \in f_{\langle w, g \rangle}^{*, X}(/ \phi / g) : \exists \langle u, k \rangle \in f_{\langle w, g \rangle}^{*, X}(/ \phi / g) : \langle u, k \rangle \sim^X \langle v, h \rangle$  and  $\langle u, k \rangle$  verifies  $\psi$ .

Notice that with this definition we can account for both strong and weak counterfactual donkey sentences. A strong counterfactual donkey sentence like (5) will be represented by  $\exists x[Px] >^{\{x\}} Qx$  and its meaning will be equivalent with that of the universal sentence  $\forall x[Px > Qx]$  just

as in the original account proposed in Sect. 3.3. A weak counterfactual donkey sentence like (7-b), on the other hand, will be represented by a formula of the form  $\exists x[Px] >^\emptyset Qx$  and is true even if in the closest counterfactual world(s) where I have more than one dime in my pocket, I throw only one of them into the meter.

## 5.2. NPI-*any* REVISITED

As suggested above, I propose that NPI-*any* should be treated as a *weak* ‘counterfactual’ donkey sentence. More in particular, the proposed (Montague-style) meaning of NPI-*any* will be  $\lambda P\lambda Q\exists x[Px] >^\emptyset Qx$ . I will show in a moment that given our interpretation of ‘ $>^X$ ’, this formula gives rise to the same truth conditions as the more standard  $\exists x[Px \wedge Qx]$  if we make one more assumption: that a sentence in which *any* with restrictor  $P$  occurs *presupposes* that  $P$  has a non-empty extension (in the world of interpretation). Notice, first, that this assumption is quite innocent for uses of U-*any* if these are analyzed as we proposed in Sect. 4. In particular, it doesn’t exclude at all that we take into account non-actual worlds to verify the sentence in which it occurs. Given our analysis of weak counterfactual donkey sentences and our proposed representation of NPI-*any*, on the other hand, this innocent looking presupposition has the very welcome effect that  $\exists x[Px] >^\emptyset Qx$  will have exactly the same truth conditions as the formula  $\exists x[Px \wedge Qx]$ , which is the standard translation of indefinites.<sup>23</sup> By K&L’s widening and strengthening analysis, this will thus have the

---

<sup>23</sup> One might complain that in this way we can’t account for sentences like *There isn’t any unicorn in the garden*. I don’t think this is a serious

effect that we predict: that NPI-*any* is, indeed, licensed almost only in DE contexts.

Let me now show why  $\exists x[Px] >^\emptyset Qx$  will have exactly the same truth conditions as the formula  $\exists x[Px \wedge Qx]$ , if  $P$  has a non-empty extension in the actual world. The first thing to notice is that because the set of variables which NPI-*any* unselectively quantifies over is empty, i.e.  $X = \emptyset$ , the ordering relation in terms of which our formula  $\exists x[Px] >^\emptyset Qx$  is interpreted comes down to the standard Lewis/Stalnaker ordering between possible worlds. With Lewis and Stalnaker we have assumed that this ordering satisfies strong centering, which means that for any two different worlds  $v$  and  $w$ ,  $w$  is always strictly more similar to itself than  $v$  is to  $w$ :  $w <_w v$ . Assuming that  $P$  has a non-empty extension in actual world  $w$  – i.e., assuming that the presupposition is satisfied – it follows by definition 5 that to verify  $\exists x[Px] >^\emptyset Qx$  we only have to consider the actual world  $w$ . Take the possibility in which the sentence is interpreted to be  $\langle w, g \rangle$ .<sup>24</sup> By definition 5 again, for  $\exists x[Px] >^\emptyset Qx$  to be true in  $\langle w, g \rangle$ , it is enough if there is a  $h$  such that  $\langle w, h \rangle \in / \exists x Px /_g$  and  $\langle w, h \rangle$  verifies  $Qx$ . But this means that there must be a  $d \in D$  such that  $h = g[x/d]$  (meaning as usual that  $h$  is just like  $g$  except that it assigns variable  $x$  to individual  $d$ ) and  $h(x) \in I_w(P)$  and  $h(x) \in I_w(Q)$  (where  $I_w(P)$  denotes the extension of  $P$  in  $w$  according to the model's interpretation function  $I$ ). But that obviously means that  $\exists x[Px] >^\emptyset Qx$  has exactly the same

---

problem, because I find this sentence appropriate only in case it is assumed (for the sake of argument) that there are unicorns.

<sup>24</sup> But notice that the identity of the assignment is quite irrelevant.

truth conditions as the formula  $\exists x[Px \wedge Qx]$ , if  $P$  has a non-empty extension, which is precisely what we wanted to show.

Given this proof, we have shown that we can treat not only U-*any* as a ‘counterfactual’ donkey sentence (in disguise), but NPI-*any* as well. The only difference is that whereas U-*any* is interpreted as a *strong* donkey sentence, NPI-*any* is interpreted as a *weak* donkey sentence. Exactly because of this, (i) U-*any* gets a *universal* interpretation and NPI-*any* an *existential* one, and thus (ii) U-*any* is via K&L’s analysis licensed only in positive contexts, while NPI-*any* is licensed (almost) only in *negative* contexts.<sup>25</sup>

I conclude that an analysis of the different uses of *any* as ‘counterfactual’ donkey sentences (in disguise) is quite successful because (i) it gives rise to (approximately) the same meanings as the successful analyses of U-*any* (Dayal) and NPI-*any* (K&L), but it allows us to treat them all in an (almost) uniform way, and reduce their differences to an independently required distinction between different readings of donkey sentences (strong versus weak).<sup>26</sup>

---

<sup>25</sup> Rooth (1987) observed that some quantified donkey sentences (e.g. ones with ‘every’) typically give rise to strong readings, whereas others (e.g. ones with ‘no’ or ‘few’) typically give rise (only) to weak readings. Is this a problem for the proposed analysis (as one reviewer wondered)? Well, we predict that *any* in examples like ‘No/few officer(s) gave *any* member of a squad its orders’ should be analyzed as a *weak* counterfactual donkey, because the item occurs in a DE context. I think this is in accordance with intuition.

<sup>26</sup> Our analysis predicts that the following comparatives with *any* are appropriate:

## 6. Free choice *any*

In the previous section we have accounted for ‘Universal’ and ‘NPI-*any*’ in a uniform way. We have not yet explained how the following free choice reading of *any* should be accounted for:

(8) You may take *any* card.

The main challenge is, of course, to account for the universal reading of (8). Given that U-*any* gives rise to a universal reading, but NPI-*any* does not, it seems reasonable to think of (8) in terms of U-*any*. The problem is that in order to get the universal reading, we have to scope the existential quantifier over the modality and represent (8)

---

(i) Mary is taller than *any* man.

(ii) *Any* man is taller than Mary.

On Seuren’s (1973) analysis of comparatives, John is taller than Mary iff  $\exists d[Tall(j, d) \wedge \neg Tall(m, d)]$ , where  $d$  is a degree and ‘*Tall*’ a relation between individuals and degrees. On this analysis, *any* occurs in a DE context in (i) and in a positive context in (ii). Applying K&L’s appropriateness condition, this means that we have to represent (i) by a formula like  $\exists d[Tall(m, d) \wedge \neg(\exists x Mx >^{\emptyset} Tall(x, d))]$ , while (ii) should be represented either by  $\exists d[(\exists x Mx >^{\{x\}} Tall(x, d)) \wedge \neg Tall(m, d)]$  or by  $\exists x Mx >^{\{x\}} (\exists d[Tall(x, d) \wedge \neg Tall(m, d)])$ . If we make the natural assumption that Tallness is monotone decreasing in degrees ( $\forall x, d, d'[(Tall(x, d) \wedge d' < d) \rightarrow Tall(x, d')]$ ) the latter two analyses are identical. Something similar happens with von Stechow’s (1984) analysis of comparatives.

as  $\exists x Cx >^{\{x\}} \text{May}(j, Tx)$ . Although this representation gives us the intuitively correct reading,<sup>27</sup> I believe the price of this unusual scoping is too high. If we want to give ‘may’ scope over the existential quantifier, however, and represent (8) by  $\text{May}(j, \exists x Cx >^{\{x\}} Tx)$ , we don’t receive the correct interpretation. This suggests that we should represent the *any* in (8) in terms of ‘ $>^{\emptyset}$ ’ instead of ‘ $>^{\{x\}}$ ’. Now the problem is that on a standard analysis of the modal, we can’t derive the universal reading.<sup>28</sup> I will suggest that this is due to a wrong choice of interpretation of ‘may’ in (8). I will show that if we analyze the permission *performatively*, as originally proposed by Lewis (1970/79) and Kamp (1979), but account for this performative analysis in a new

---

<sup>27</sup> If we assume that the ordering between worlds required to analyze the conditional connective ‘ $>$ ’ is such that  $v <_w u$  iff  $I(C)(w) \subseteq I(C)(v) \subset I(C)(u)$ , we make the same predictions as the system proposed by Menendez-Benito (2005), who makes use of universal quantification and an exclusiveness operator. See Sect. 7 for more discussion.

<sup>28</sup> Quite a number of authors (e.g. Kratzer and Shimoyama 2002, Schulz 2005, Fox 2006) have proposed to account for the ‘conjunctive’ implication of a sentence like ‘You may take an apple or a pear’ in terms of conversational implicatures. Thus one might propose (e.g. Chierchia 2006, Aloni and van Rooij 2007) to account for the universal reading of (8) by means of a conversational implicature as well. However, conversational implicatures are cancelable, and the universal reading of (8) is not, which suggests (to me) that the universal reading of this sentence should not be accounted for by a Gricean implicature after all.

*distributive* way, we can derive the universal reading of (8) and can explain why domain widening gives rise to a stronger reading.

According to the performative account, if the master commands John to do  $\phi$  by saying ‘You must do  $\phi$ ’, or allows John to do  $\phi$  by saying ‘You may do  $\phi$ ’, it is typically not yet the case that the proposition expressed by  $\phi$  is respectively a superset of, or consistent with, John’s permissibility set,  $\Pi$ , represented by a set of possible worlds. However, the performative effect of the command/permission will be such that in the new context what is commanded is a superset of, and what is permitted is consistent with, the new permissibility set. Thus, in case the command or permission is not used vacuously, the permissibility set,  $\Pi'$ , of the new context will be different from  $\Pi$ , so that the obligation/permission sentence will be satisfied. Our problem is to say how command and permission sentences govern the change from the prior permissibility set,  $\Pi$ , to the posterior one,  $\Pi'$ .

Kamp (1979) proposed to solve this problem by assuming that the change from prior to posterior permission set is governed by (what is now called) *revision* and *contraction*. The idea is that we not only have a set of best, or ideal, worlds, but also a global *reprehensibility ordering* that says which non-ideal worlds are better than others. It is well known that such an analysis can account for the free choice effect of permission sentences like ‘You may take an apple or a pear’, but only in case taking apples and taking pears is equally reprehensible. Although this proposal is very natural, it is not quite good enough to account for the free choice effect of ‘You may take *any* apple’ (if ‘any’ is represented by an existential quantifier). On Kamp’s performative analysis one can only conclude from this sentence that one is allowed

to take apple  $a$  iff apple  $a$  is among the least reprehensible ones to take. The free choice effect seems to be stronger, though, and independent of a reprehensibility ordering. Van Rooij (2006a) proposed to tackle this problem by assuming that the change from prior to posterior permission state is sensitive to the assignments as well. Here we will follow a recent suggestion by Schulz (2008) to account for the update effect of permissions in terms of a *local* instead of a *global* ordering relation between worlds. The local ordering relation is the standard one used in premise semantics: given a set of formulas  $\Psi$ , we define  $v$  to be at least as ‘good’ as  $w$ ,  $w \leq_{\Psi} v$ , iff all formulas in  $\Psi$  true in  $w$  are also true in  $v$ .

$$w \leq_{\Psi} v \quad \text{iff}_{def} \quad \forall \psi \in \Psi : w \models \psi \Rightarrow v \models \psi$$

In terms of this ordering relation, we now define a function that assigns to a world  $w$  and a formula  $\phi$  the  $\phi$ -worlds which are minimal extensions of  $w$ :

$$f_{\leq}(w, \phi) \stackrel{def}{=} \{v \in \llbracket \phi \rrbracket : w \leq v \ \& \ \neg \exists u \in \llbracket \phi \rrbracket : w \leq u \ \& \ u < v\}$$

The idea is that if we previously were in allowed world  $w$  and are now allowed to make  $\phi$  true, we are allowed to go to any  $\phi$ -worlds that are minimal extensions of  $w$ . As in standard dynamic semantics, we assume that the (performativ) effect of a permission sentence is modeled as a function from prior to posterior permission set. In fact, following Schulz (2008) we will make use of a partial semantics here. The positive update function of a permission with respect to permission set  $\Pi$  is defined by means of this choice function given above:

$$\Pi[\text{May } \phi]^+ \stackrel{def}{=} \Pi \cup \bigcup_{w \in \Pi} f(w, \phi)$$

Thus, the result of the permission is that new worlds are added to the prior permission set. The negative update of the same sentence does the reverse: it eliminates  $\phi$ -worlds from the permission set.

$$\Pi[\text{May } \phi]^- \stackrel{def}{=} \Pi - \bigcup_{w \in \Pi} f(w, \phi)$$

This definition of the positive and negative update functions wouldn't be complete without a recursive definition of the meaning of the sentential connectives. This recursive definition is given below:

$$\begin{array}{ll} \Pi[\neg\phi]^+ \stackrel{def}{=} \Pi[\phi]^- & \Pi[\neg\phi]^- \stackrel{def}{=} \Pi[\phi]^+ \\ \Pi[\phi \wedge \psi]^+ \stackrel{def}{=} \Pi[\phi]^+ [\psi]^+ & \Pi[\phi \wedge \psi]^- \stackrel{def}{=} \Pi[\phi]^- \cup \Pi[\psi]^- \end{array}$$

If we now define 'v' in terms of '¬' and '∧' as usual, and also define the update with 'Must' in terms of the update with 'May' in the standard way:

$$\Pi[\text{Must } \phi]^+ \stackrel{def}{=} \Pi[\neg \text{May } \neg\phi]^+ \quad \Pi[\text{Must } \phi]^- \stackrel{def}{=} \Pi[\neg \text{May } \neg\phi]^- ,$$

we receive the appealing result that  $\Pi[\text{Must } \phi]^+ = \Pi \cap [\phi]$ .

To account for entailments between permission sentences, Kamp (1979) proposed the notion of  $p$ -entailment. It says that 'May  $\psi$ ' follows

from ‘May  $\phi$ ’ ( $May(j, \phi) \models^p May(j, \psi)$ ) iff adding the permission that  $\psi$  doesn’t change the permission set anymore after you were permitted to do  $\phi$ . On our new dynamic analysis, this means that the permission of  $\psi$  follows from the permission of  $\phi$  iff<sub>def</sub> for all permission states,  $\Pi$ :  $\Pi[\phi]^+ = \Pi[\phi]^+[\psi]^+$ . Notice that in case  $Q(a)$  and  $Q(b)$  are elements of the set  $\Psi$  in terms of which the ordering relation is defined, it follows that  $May(j, Q(a) \vee Q(b)) \models_d May(j, Q(a)) \wedge May(j, Q(b))$ . If it is also the case that  $Q(c)$  is an element of  $\Psi$ ,  $May(j, Q(c))$  doesn’t follow from  $May(j, Q(a) \vee Q(b))$ . However,  $May(j, Q(c))$  *does* follow from  $May(j, Q(a) \vee Q(b) \vee Q(c))$ . This is crucial for us to account for the universal ‘reading’ of (8).

We have seen above that on our suggested representation of (8) by  $May(j, \exists xPx >^{\emptyset} Qx)$ , the embedded clause of (8) is truth-conditionally equivalent with  $\exists xPx \wedge Qx$  for worlds in  $\Pi$  that satisfy the presupposition that predicate  $P$  has a non-empty extension. Thinking of this existential sentence as a (large) disjunction, and making use of the above reasoning, we have accounted for the free choice effect of (8). Moreover, on our analysis it follows that the permission to take a(ny) card is strengthened if one extends the domain:  $May(j, \exists x_D Px) \models^p May(j, \exists x_{D'} Px)$  if  $D \supset D'$ . This means that on Kadmon and Landman’s analysis of *any*, we have explained why this item is licensed in permission sentences.

Dayal forcefully argued that any analysis of *any* has to account for the contrast between the acceptability of (8) versus the unacceptability of (9):

(9) \*You must take *any* card.

On our proposed analysis this follows immediately on the obvious extension of Kamp's notion of  $p$ -entailment to commands:  $Must(j, \phi) \models^p Must(j, \psi)$  iff adding the obligation that  $\psi$  doesn't change the permission set anymore after you were obliged to do  $\phi$ .<sup>29</sup> To see that this follows, notice that the update of  $\Pi$  with  $Must(j, \exists_D Qx)$ , i.e.  $\Pi \cap [\exists_D Qx]$ , doesn't have to entail the following formula,  $\exists_{D'} Qx$ , where  $D' \subset D$ . For if  $D = \{a, b, c\}$ , and the worlds in  $\Pi$  where John takes cards  $a$ ,  $b$ , and  $c$  are  $w_1$ ,  $w_2$ , and  $w_3$ , respectively,  $\Pi \cap [\exists_D Qx]$  will be  $\{w_1, w_2, w_3\}$ , while  $\Pi \cap [\exists_{D'} Qx]$ , with  $D' = \{a, b\} \subset \{a, b, c\} = D$ , will be  $\{w_1, w_2\}$ . Thus, after the obligation of  $\exists_D Qx$  the permission set will still change when you get the obligation that  $\exists_{D'} Qx$ . But this means that domain extension *does not* result in a stronger obligation, which means that K&L's constraint for the appropriate use of *any* is not met.<sup>30</sup>

---

<sup>29</sup> Kamp's notion of  $p$ -entailment and this extension are both special cases of Veltman's (1996) more general entailment relation between speech acts.

<sup>30</sup> As noted by Giannikidou (2001), among others, in direct commands, *any* can be used appropriately:

- (i) Take *any* card.

Intuitively, (i) means 'You must take a card, it doesn't matter which.' If we would analyze (9) and (i) in the same way, we wouldn't be able to account for the contrast, obviously. I would suggest that (9) is inappropriate but (i) is not because only the latter expresses a command and permission at the same time; the former expresses (or wants to express) just a command.

## 7. Comparison and conclusion

Negative polarity and free choice items are hotly debated in the literature. But apart from the papers of Dayal and K&L (and Krifka), I haven't made much reference to this discussion in this paper. Although it is impossible to do justice to all proposed analyses, in this final section I will briefly relate my analysis to at least some other analyses not discussed so far, and lay out some possible modifications and extensions.

A prominent analysis of crosslinguistic (variants of) *any* is proposed in various papers of Anastasia Giannakidou. Like us, she argues for an existential analysis of *any*, but seeks to account for its appropriateness in terms of licensing conditions in the style of Ladusaw (1979). In Giannakidou (2001), for instance, it is claimed that NPI-*any* is licensed in non-veridical contexts, while FC-*any* (including our U-*any*) also demands that the context be episodic. Giannakidou argues against Ladusaw's analysis with an impressive battery of counterexamples, but at least some of these counterexamples can be accounted for by other approaches that distinguish between the several potential meanings of *any* (like K&L and Dayal). I won't discuss these examples here, but just want to note that Giannakidou as well makes use of a (strict) conditional to account for U-*any*, following Legrand (1975). Indeed, one can account for the intuition that U-*any* is stronger than *every* by treating it in terms of a strict conditional that quantifies over worlds. However, it doesn't seem to be possible – in contrast to our analysis in terms of counterfactual connective '>' – to give a similar treatment of NPI-*any* in terms of strict conditionals such that this item gives

rise to its standard existential meaning.<sup>31</sup> In this sense, Legrand's and Giannakidou's analyses of *any* will end up being less uniform than ours.

A semantically uniform analysis of both uses of *any* has been proposed by Chierchia (2006), modified by Aloni and van Rooij (2007).<sup>32</sup> Chierchia follows K&L in their analysis of *any* as an ordinary indefinite, with reliance on the 'widening-leads-to-strengthening' condition, but seeks to account for U-*any* by conversational implicature rather than by appealing to genericity. Thinking of an existential sentence as a large disjunction, Chierchia (2006) proposes that ' $A \vee B$ ' gives rise to the conversational implicature that the speaker doesn't know that ' $A \wedge \neg B$ ' is true and doesn't know that ' $\neg A \wedge B$ ' is true. By assuming that the speaker knows what he is talking about, we can conversationally implicate that the speaker knows that both conjunctions are false, and thus that ' $A \wedge \neg B$ ' and ' $\neg A \wedge B$ ' are both false. But in conjunction with the assertion this means that it has to be the case that ' $A \wedge B$ ' is true. Although appealing, I believe (on second thought) that such an approach is problematic, for two reasons. First of all, it does not really account for the 'that-can't-be-an-accident' force of the universal reading. Second, it assumes that the relevant conversational implicatures are *uncancelable*, which goes against the very idea of something being an implicature in the first place. Most naturally, what can be cancelled is the assumption that the speaker is knowledgeable: the step from 'not know  $A$ ' to 'know not  $A$ '. Applying cancelability to Chierchia's reasoning, however, would make the wrong prediction: it is predicted that the U-*any* sentence can be true, although at the same time the speaker doesn't know that the

---

<sup>31</sup> That is, without making strong ad hoc assumptions.

<sup>32</sup> For a related approach, see Abrusan (2006).

universal statement is true. So, with Jayez and Tovena (2005), I would argue against an analysis that accounts for the universal force of U-*any* in terms of a conversational implicature.

Where Chierchia wants to derive the strong reading of U-*any* by making strong knowledge assumptions, Jayez and Tovena (2005) and others would rather like to infer universality from one's *lack of knowledge*, or from one's *indifference*. In fact, this assumption is not very different from Dayal's (1998) *vagueness requirement*. Dayal argues that 'John talked to any of these women' is bad because in order for the speaker to know that the sentence is true, the speaker has to know of each of the individual women he is looking at that John talked to her. But this requirement violates Dayal's vagueness constraint on the quantificational domain of U-*any* that the speaker should not know (or care about, we might add) exactly (roughly speaking) who he was talking about. Part of this irrelevance or lack of knowledge requirement we have already accounted for by our 'counterfactual' analysis: to see whether a sentence of the form ' $\exists x[Px] >^{\{x\}} Qx$ ' is true we can't limit ourselves to the individuals who actually have property *P*. In fact, given that Dayal's treatment of *whatever* (Dayal 1997) is so close to her analysis of FC-*any* – and because of Legrand's (1975) claim that free relatives combined with *wh-ever* are semantically equivalent to *any* combined with a relative clause – it looks attractive to account for the universal reading of sentences like 'John voted for *whoever* was on top of the ballot' in terms of a 'counterfactual' donkey analysis as well.<sup>33</sup>

---

<sup>33</sup> Though following observations of Jacobson (1995) and others, we should perhaps allow the variable to range over pluralities now. This would also account for Choi's observation (p.c.) that you may take

Another part we have not accounted for yet: that the speaker doesn't know, or care about, which individuals actually have property  $P$ . I don't see any harm being done if we add this constraint as a presupposition for the use of universal (or perhaps of any?) uses of *any*.

Two final papers I would like to mention are Menendez-Benito (2005) and Aloni (2006). Both assume that occurrences of free choice *any* (or their Spanish and Italian counterparts) should be interpreted as *indeterminate pronouns* along the lines of Kratzer and Shimoyama's (2002) analysis of German existential free choice items. According to their proposals, the free choice item introduces a set of (Hamblian) alternative propositions, and the universal interpretation is guaranteed by assuming that at top level we universally quantify over the alternative propositions. Interestingly, they explain why *any* is appropriate under *may* but not under *must* by assuming that the propositional alternatives are mapped into a set of mutually exclusive propositions because of an *exclusiveness* (Menendez-Benito 2005) or an *exhaustivity* operator (Aloni 2006). This exclusiveness is consistent with the existential meaning of *may*, but not with the universal meaning of *must*. Although neither of these approaches can really account for the 'that-can't-be-an-accident' force of U-*any*, I think they give rise to empirical predictions very similar to my approach. However, I would like to claim that my proposal depends on (arguably) less controversial assumptions: in contrast to them, I don't need a Hamblin-style semantics for indefinites, propositional alternatives, or a covert universal quantification over propositional alternatives. Most of all, however, their assumption more than one thing after the permission 'You may take whatever is given to you.'

that we need a covert exclusiveness or exhaustivity operator to account for free choice permissions like (8) is not needed, because exclusiveness *follows* from my treatment: we are looking for *minimally* different worlds (from a world, or set of worlds, where *no* card is taken). If (8) is analyzed in terms of U-*any* –  $\exists x Cx >^{\{x\}} \text{May } Tx$ – exclusiveness is due to the meaning of the counterfactual connective; if (8) is analyzed in terms of NPI-*any* and a performative analysis, exclusiveness follows from a minimal change of the permission set.

In this paper I have limited myself to the use of the English item *any*. This is probably still the most discussed word in any discussion of negative polarity and/or free choice items. However, more recently people have become very interested in the issue how negative polarity and free choice items are expressed in languages other than English, and discovered that there exists large variability (see Choi 2007 and Vlachou 2007 for two extensive recent studies). I would have liked to explore what my analysis of *any* might have to offer on the issue of language variability, but I'm afraid I am not competent enough on these matters to enter into such discussions and leave that to others. I will also leave to others the proposal to take the two *any*'s to be even more look-alike than what is proposed in this paper, by assuming that semantically speaking *all* donkey sentences have only weak truth conditions, and accounting for the strong readings in terms of pragmatics.
