Plan for Today

To illustrate a further application of the *axiomatic method*, today we are going to review three of the classical *impossibility theorems* in the domain of voting and preference aggregation:

- *Arrow’s Theorem* (1951)
- *Sen’s Theorem* on the Impossibility of a Paretian Liberal (1970)
- the *Muller-Satterthwaite Theorem* (1977)

They all show that it is impossible to simultaneously satisfy certain intuitively appealing axioms when designing a voting rule.

Full details of all proofs are available in my review paper (cited below).

Warm-Up

Given a finite set $N = \{1, \ldots, n\}$ of voters and a finite set $A$ of alternatives, we are looking for a voting rule:

$$F : \mathcal{L}(A)^n \to 2^A \setminus \{\emptyset\}$$

Exercise: Show that it is impossible to find a voting rule for two voters and two alternatives that is resolute, anonymous, and neutral.
Axiom: The Pareto Principle

A voting rule $F$ is called (weakly) \textit{Paretian} if, whenever all voters rank alternative $x$ above alternative $y$, then $y$ cannot win:

$$N^R_{x \succeq y} = N \text{ implies } y \notin F(R)$$
Axiom: The Principle of Liberalism

Think of $A$ as the set of all possible “social states”. Certain aspects of such a state will be some individual’s private business. **Example:**

If $x$ and $y$ are identical states, except that in $x$ I paint my bedroom white, while in $y$ I paint it pink, then I should be able to dictate the relative social ranking of $x$ and $y$.

**Remark:** For examples of this kind, it makes more sense to think of $F$ as a “social choice function” rather than a “voting rule”.

$F$ is called *liberal* if, for every individual $i \in N$, there exist two distinct alternatives $x, y \in A$ such that $i$ is **two-way decisive** on $x$ and $y$:

$$i \in N^R_{x \succ y} \text{ implies } y \not\in F(R) \text{ and } i \in N^R_{y \succ x} \text{ implies } x \not\in F(R)$$
The Impossibility of a Paretian Liberal

Bad news:

**Theorem 1 (Sen, 1970)** *For $|N| \geq 2$, there exists no social choice function that is both Paretian and liberal.*

As we shall see, the theorem holds even when liberalism is enforced for only two individuals. The number of alternatives does not matter.

Proof Sketch

Let $F$ be a SCF that is Paretian and liberal. Get a contradiction:

Take two distinguished individuals $i_1$ and $i_2$, with:

- $i_1$ is two-way decisive on $x_1$ and $y_1$
- $i_2$ is two-way decisive on $x_2$ and $y_2$

Assume $x_1, y_1, x_2, y_2$ are pairwise distinct (other cases: easy).

Consider a profile with these properties:

(1) Individual $i_1$ ranks $x_1 \succ y_1$.
(2) Individual $i_2$ ranks $x_2 \succ y_2$.
(3) All individuals rank $y_1 \succ x_2$ and $y_2 \succ x_1$.
(4) All individuals rank $x_1, x_2, y_1, y_2$ above all other alternatives.

From liberalism: (1) rules out $y_1$ and (2) rules out $y_2$ as winner.
From Pareto: (3) rules out $x_1$ and $x_2$ and (4) rules out all others.

Thus, there are no winners. Contradiction. $\checkmark$
Resolute Social Choice Functions

For the remainder of today, we focus on resolute SCF’s:

\[ F : \mathcal{L}(A)^n \to A \]

The axioms we have seen already can be easily adapted to this slightly simpler model. For example, this is the Pareto Principle:

\[ N_{x \succeq y}^R = N \text{ implies } y \neq F(R) \]

The next result we are going to see, Arrow’s Theorem, originally got formulated for so-called social welfare functions instead:

\[ F : \mathcal{L}(A)^n \to \mathcal{L}(A) \]

This change in framework does not affect the essence of the result, and it makes it fit better with our overall storyline . . .
**Axiom: Independence of Irrelevant Alternatives**

If alternative $x$ wins and $y$ does not, then $x$ is *socially preferred* to $y$. If both $x$ and $y$ lose, then we cannot say.

Whether $x$ is socially preferred to $y$ should *depend* only on the relative rankings of $x$ and $y$ in the profile (not on other, irrelevant, alternatives).

These considerations motivate our next axiom:

$F$ is called *independent* if, for any two profiles $R, R' \in \mathcal{L}(A)^n$ and any two distinct alternatives $x, y \in A$, it is the case that $N^R_{x \succ y} = N^{R'}_{x \succ y}$ and $F(R) = x$ imply $F(R') \neq y$.

Thus, if $x$ prevents $y$ from winning in $R$ and the relative rankings of $x$ and $y$ remain the same, then $x$ also prevents $y$ from winning in $R'$. 
**Arrow’s Impossibility Theorem**

A resolute SCF $F$ is a *dictatorship* if there exists an $i \in N$ such that $F(R) = \text{top}(R_i)$ for every profile $R$. Voter $i$ is the dictator.

The seminal result in SCT, here adapted from SWF’s to SCF’s:

**Theorem 2 (Arrow, 1951)** Any resolute SCF for $\geq 3$ alternatives that is Paretian and independent must be a dictatorship.

Remarks:

- You should be surprised by this and refuse to believe it (for now).
- Not true for $m = 2$ alternatives. *(Why?)*
- Common misunderstanding: dictatorship $\neq$ “local dictatorship”
- Impossibility reading: independence + Pareto + nondictatoriality
- Characterisation reading: dictatorship $=$ independence + Pareto

Proof Plan

For full details, consult my review paper, which includes proofs both for SWF’s and SCF’s (the latter within the proof for the M-S Thm).

Let $F$ be a SCF for $\geq 3$ alternatives that is Paretian and independent.

Call a coalition $C \subseteq N$ decisive for $(x, y)$ if $C \subseteq N_{x \succ y} \Rightarrow y \neq F(R)$.

We proceed as follows:

- **Pareto** condition = $N$ is decisive for all pairs of alternatives
- $C$ with $|C| \geq 2$ **decisive** for all pairs $\Rightarrow$ some $C' \subset C$ as well
- By induction: there’s a decisive coalition of size 1 ($= \text{dictator}$).

Remark: Observe that this only works for finite sets of voters. (*Why?*)

The step in the middle of the list is known as the **Contraction Lemma**.

To prove it, we first require another lemma . . .

Contagion Lemma

Recall: \( C \subseteq N \) decisive for \((x, y)\) if \( C \subseteq N^R_{x \succ y} \implies y \neq F(R) \)

Call \( C \subseteq N \) weakly decisive for \((x, y)\) if \( C = N^R_{x \succ y} \implies y \neq F(R) \).

Claim: \( C \) weakly decisive for \((x, y)\) \( \implies \) \( C \) decisive for all pairs \((x', y')\).

Proof: Suppose \( x, y, x', y' \) are all distinct (other cases: similar).

Consider a profile where individuals express these preferences:

- Members of \( C \): \( x' \succ x \succ y \succ y' \)
- Others: \( x' \succ x, y \succ y' \), and \( y \succ x \) (note: \( x'\)-vs.-\( y' \) not specified)
- All rank \( x, y, x', y' \) above all other alternatives.

From \( C \) being weakly decisive for \((x, y)\): \( y \) must lose.

From Pareto: \( x \) must lose (to \( x' \)) and \( y' \) must lose (to \( y \)).

Thus, \( x' \) must win (and \( y' \) must lose). By independence, \( y' \) will still lose when everyone changes their non-\( x'\)-vs.-\( y' \) rankings.

Thus, for every profile \( R \) with \( C \subseteq N^R_{x' \succ y'} \) we get \( y' \neq F(R) \). \( \checkmark \)
**Contraction Lemma**

**Claim:** If $C \subseteq N$ with $|C| \geq 2$ is a coalition that is decisive on all pairs of alternatives, then so is some nonempty coalition $C' \subset C$.

**Proof:** Take any nonempty $C_1, C_2$ with $C = C_1 \cup C_2$ and $C_1 \cap C_2 = \emptyset$.

Recall that there are $\geq 3$ alternatives. Consider this profile:

- Members of $C_1$: $x \succ y \succ z \succ \text{rest}$
- Members of $C_2$: $y \succ z \succ x \succ \text{rest}$
- Others: $z \succ x \succ y \succ \text{rest}$

As $C = C_1 \cup C_2$ is decisive, $z$ cannot win (it loses to $y$). Two cases:

1. The winner is $x$: Exactly $C_1$ ranks $x \succ z \Rightarrow$ By independence, in any profile where exactly $C_1$ ranks $x \succ z$, $z$ will lose (to $x$) $\Rightarrow C_1$ is weakly decisive on $(x, z)$. So by Contagion Lemma: $C_1$ is decisive on all pairs.

2. The winner is $y$, i.e., $x$ loses (to $y$). Exactly $C_2$ ranks $y \succ x \Rightarrow \cdots \Rightarrow C_2$ is decisive on all pairs.

Hence, one of $C_1$ and $C_2$ will always be decisive. $\checkmark$
Axioms: Weak and Strong Monotonicity

Two axioms for a resolute SCF $F$:

- $F$ is called **weakly monotonic** if $x^* = F(R)$ implies $x^* = F(R')$ for any alternative $x^*$ and any two profiles $R$ and $R'$ with $N_{x^* > y}^R \subseteq N_{x^* > y}^{R'}$ and $N_{y > z}^R = N_{y > z}^{R'}$ for all $y, z \in A \setminus \{x^*\}$.

- $F$ is called **strongly monotonic** if $x^* = F(R)$ implies $x^* = F(R')$ for any alternative $x^*$ and any two profiles $R$ and $R'$ with $N_{x^* > y}^R \subseteq N_{x^* > y}^{R'}$ for all $y \in A \setminus \{x^*\}$.

A good way to remember the difference:

- **weak monotonicity** = raising the winner preserves the winner
- **strong monotonicity** = lowering a loser preserves the winner

Strong monotonicity is also known as Maskin monotonicity.
Example

Even *weak monotonicity* is not satisfied by some common voting rules.

Under *plurality with runoff* the two alternatives with the highest plurality score enter a second round and the majority winner of that round is the winner (used to elect the French president). **Example:**

<table>
<thead>
<tr>
<th>Voters</th>
<th>Preference</th>
</tr>
</thead>
<tbody>
<tr>
<td>27</td>
<td>$a \succ b \succ c$</td>
</tr>
<tr>
<td>42</td>
<td>$c \succ a \succ b$</td>
</tr>
<tr>
<td>24</td>
<td>$b \succ c \succ a$</td>
</tr>
</tbody>
</table>

So $b$ is eliminated in the first round and $c$ beats $a$ 66:27 in the runoff.

But if 4 of the voters in the first group *raise $c$ to the top*, then $b$ wins.

But many other rules (e.g., *plurality*) do satisfy weak monotonicity. How about *strong monotonicity*?
The Muller-Satterthwaite Theorem

More bad news:

**Theorem 3 (Muller and Satterthwaite, 1977)** Any resolute SCF for $\geq 3$ alt. that is surjective and strongly monotonic is a dictatorship.

Here, a resolute SCF $F$ is called *surjective* (or *nonimposed*) if for every alternative $x \in A$ there exists a profile $R$ such that $F(R) = x$.

**Exercise:** Show that surjectivity is required for this theorem to hold.

**Proof:** Next, we are going to show:

- strong monotonicity implies independence
- surjectivity and strong monotonicity imply the Pareto Principle

The claim then follows from Arrow’s Theorem. ✓

Deriving Independence

Recall: $F$ is independent if, for $x \neq y$, we have that $N^R_{x \succ y} = N^{R'}_{x \succ y}$ and $F(R) = x$ together imply $F(R') \neq y$.

Claim: If $F$ is strongly monotonic, then $F$ is also independent.

Proof: Suppose $F$ is SM, $x \neq y$, $N^R_{x \succ y} = N^{R'}_{x \succ y}$, and $F(R) = x$.

Construct a third profile $R''$:

- All individuals rank $x$ and $y$ in the top-two positions.
- The relative rankings of $x$ vs. $y$ are as in $R$, i.e., $N^{R''}_{x \succ y} = N^R_{x \succ y}$.
- Rest: whatever

By strong monotonicity, $F(R) = x$ implies $F(R'') = x$.

By strong monotonicity, $F(R') = y$ would imply $F(R'') = y$.

Thus, we must have $F(R') \neq y$. ✓
Deriving the Pareto Principle

Recall: $F$ is Paretian if $N^R_{x \succ y} = N$ implies $F(R) \neq y$.

Claim: If $F$ is surjective and SM, then $F$ is also Paretian.

Proof: Suppose $F$ is surjective and SM (and thus also independent).

Take any two alternatives $x$ and $y$.

From surjectivity: $x$ will win for some profile $R$.

Starting in $R$, have everyone move $x$ above $y$ (if not above already).

From strong monotonicity: $x$ still wins.

From independence: $y$ does not win for any profile where all individuals continue to rank $x \succ y$. ✓
The Bigger Picture

As a deeper analysis reveals, Arrovian impossibilities arise as the result of the interaction of two forces:

- **Axioms**, particularly independence, that directly constrain the behaviour of the aggregation rule.

- **Collective rationality**, i.e., the requirement for the output to satisfy certain structural requirements (here: having a single winner).

This perspective is useful for COMSOC and AI, as it helps understand the dynamics of aggregating other types of structures, such as social networks, argument graphs, or nonstandard (incomplete) preferences.

Summary

Making heavy use of the *axiomatic method*, we have presented and proved three of the classic *impossibility theorems* of SCT. They all establish the incompatibility of certain desirable axioms:

- **Sen**: Pareto and liberalism
- **Arrow**: Pareto and independence
- **Muller-Satterthwaite**: surjectivity and strong monotonicity

In one case, the combination in question is completely impossible, in the other two it leads to a dictatorship for resolute voting rules.

**What next?** More axiomatic method, to analyse strategic behaviour.
